

## **ABSTRACT**

A device for storing multiple bathroom implements that includes a housing having four vertical walls, wherein one of the vertical walls is partly or mostly open, and wherein the housing further includes a detachable base and an internal support member for receiving and supporting one of the cleaning implements. A front panel is attached, by hinge means, to the bottom portion of the open side of the housing at one end and includes, at its opposite end, a channel that is specifically designed to receive and support one of the cleaning implements. The first cleaning implement is a plunger that includes a handle-mounted splash guard, the geometry of which corresponds to the shape and dimensions of the internal support member within the housing. The second cleaning implement is a toilet brush that also includes a handle-mounted splash guard, the geometry of which corresponds to the shape and the dimensions of the channel that is formed in the front panel. The handles of the brush and the plunger cooperate to form an assembly wherein the brush sits adjacent to the plunger within the housing, and wherein the head of the brush is offset from the head of the plunger.
